SS is a rare leukemic type of CTCL, traditionally defined by the triad of pruritic erythroderma, generalized lymphadenopathy, and clonally related neoplastic T cells with cerebriform nuclei (Sezary cells) in the skin, lymph nodes, and peripheral blood.

Table 1. Relative frequency and prognosis of primary cutaneous lymphomas included in the 2018 update of the WHO-EORTC classification

Marinos,[2] A. Oikonomidi,[2] A. Stratigos,[2] M.-D. Vignon-Pennamen,[2] M. Battistella,[2] F. Climent,[2] E. Gonzalez-Barca,[2] E. Georgiou,[2]

What's already known about this topic?

- Mycosis fungoides (MF) is a rare skin cancer that may closely mimic common inflammatory dermatoses in early-stage disease.
- There is no singular diagnostic test for MF.
- Diagnosis of early-stage MF requires close clinical, pathological and genotypic correlation.

What does this study add?

- This study reports on the clinical characteristics of a large international cohort of patients with early-stage MF whose diagnosis has been confirmed following clinicopathological review.
- The median age of presentation is 57 years, which is significantly younger than those presenting with advanced-stage MF (66 years).
- This study confirmed a worldwide male predominance in early-stage MF (1·7 males : 1 female).
- A diagnostic delay is frequent (median 3 years).

Early clinical manifestations of Sézary syndrome: A multicenter retrospective cohort study

Aaron R. Mangold, MD,[a] Agnieszka K. Thompson, MD,[b,c] Mark D. Davis, MD,[b] Ieva Saulite, MD,[d] Antonio Cozzio, MD,[d,e] Emmanuella Guenova, MD, PhD,[d,e] Emmilia Hodak, MD, PhD,[f] Iris Amitay-Laish, MD,[f] Ramon M. Pujol, MD, PhD,[g] Mark R. Pittelkow, MD,[b] and Robert Gniadecki, MD, PhD[h,i]
Scottsdale, Arizona; Rochester, Minnesota; New York, New York; Zurich and St. Gallen, Switzerland; Petah Tikva, Israel; Barcelona, Spain; Edmonton, Canada; and Copenhagen, Denmark

Background: Classic Sézary syndrome (SS) is defined by erythroderma, generalized lymphadenopathy, and leukemic blood involvement. Clinical observations suggest that SS begins as a nonerythrodermic disease.

Objective: To describe the early clinical characteristics of patients with SS.

Methods: A retrospective, multicenter chart review was performed for 263 confirmed cases of SS diagnosed during 1976-2015.

Results: Erythroderma was the earliest recorded skin sign of SS in only 25.5% of cases, although most patients (86.3%) eventually developed erythroderma. In patients without erythroderma during their initial visit, the first cutaneous signs of SS were nonspecific dermatitis (49%), atopic dermatitis-like eruption (4.9%), or patches and plaques of mycosis fungoides (10.6%). The mean diagnostic delay was 4.2 years overall, 2.2 years for cases involving erythroderma at the initial presentation, and 5.0 years for cases not involving erythroderma at the initial presentation.

Limitations: This study is retrospective.

Conclusion: Erythroderma is uncommon as an initial sign of SS. Early SS should be considered in cases of nonerythrodermic dermatitis that is refractory to conventional treatments. In these cases, examination of the blood by PCR for monoclonal T-cell receptor rearrangement and by flow cytometry to identify an

CAPSULE SUMMARY

- Sézary syndrome (SS) is defined by erythroderma, generalized lymphadenopathy, and the presence of leukemic blood involvement.
- Forty-nine percent of patients with SS had a nonspecific dermatitis as the earliest cutaneous sign, and only 25.5% had erythroderma.
- Early SS should be considered in cases of nonerythrodermic, refractory dermatitis.

Key Points

- Individual patients with Sézary syndrome contain several distinct malignant subpopulations and show marked single-cell heterogeneity.

Sézary syndrome (SS) is an aggressive leukemic variant of cutaneous T-cell lymphoma (CTCL) with a median life expectancy of less than 4 years. Although initial treatment responses are often good, the vast majority of patients with SS fail to respond to ongoing therapy. We hypothesize that malignant T cells are highly heterogeneous and harbor subpopulations of SS cells that are both sensitive and resistant to treatment. Here, we investigate the presence of single-cell heterogeneity and resistance to histone deacetylase inhibitors (HDACi) within primary malignant T cells from patients with SS. Using single-cell RNA sequencing and flow cytometry, we find that malignant T cells from all investigated patients with SS display a high degree of single-cell heterogeneity at both the mRNA and

Histopathological and immunophenotypical criteria for the diagnosis of Sézary syndrome in differentiation from other erythrodermic skin diseases: a European Organisation for Research and Treatment of Cancer (EORTC) Cutaneous Lymphoma Task Force Study of 97 cases

C.D. Klemke,[1] N. Booken,[1] C. Weiss,[2] J.P. Nicolay,[1] S. Goerdt,[1] M. Felcht,[1] C. Géraud,[1] W. Kempf,[3] C. Assaf,[4] N. Ortonne,[5] M. Battistella,[6] M. Bagot,[7] R. Knobler,[8] P. Quaglino,[9] B. Arheiliger,[10] M. Santucci,[11] P. Jansen,[12] M.H. Vermeer[12] and R. Willemze[12]

What does this study add?

- Histology of SS skin biopsies revealed a significantly increased degree of epidermotropism and more intraepidermal atypical lymphocytes compared with EID, and Pautrier microabscesses were seen only in SS samples.
- The lymphocytic infiltrate in SS skin samples was found significantly to express PD-1, MUM-1 and Ki-67, and showed less infiltration of $CD8^+$ lymphocytes.

IVB	14	0.9	1.4	18	NR	NR	18	NR	NR	82	NR	NR

Abbreviations: ISCL, International Society for Cutaneous Lymphomas; EORTC, European Organisation for Research and Treatment of Cancer; OS, overall survival; DSS, disease-specific survival; RDP, risk of disease progression; NR, not reached; MF, mycosis fungoides; SS, Sézary syndrome; LyP, lymphomatoid papulosis; LDH, lactate dehydrogenase.

*LDH results based on subset of 435 patients.

†Stage T3 and T4(T3) only.

‡B0 represents those patients without *TCR* data.

§B1 represents combined data on B1 + B1a + B1b in view of small numbers.

Overall Survival in Mycosis Fungoides: A Systematic Review and Meta-Analysis

Journal of Investigative Dermatology (2019) ■, ■–■; doi:10.1016/j.jid.2019.07.712

TO THE EDITOR

Mycosis fungoides (MF) is the most common cutaneous T-cell lymphoma that confers significant mortality in advanced-stage disease (Suzuki et al., 2010; Vollmer, 2014). Although stage-specific survival data are available from different cohorts, there have been no attempts to combine existing overall survival (OS) data in this disease (Suzuki et al., 2010). Moreover, the hitherto published OS data are presented as Kaplan-Meier curves and mortality risks, which are of limited utility for the patients who prefer to have an estimate of their chances of survival (Kiely et al., 2011). The patients prefer prognostic information in terms of survival, not mortality, for example, "the chance to live 5 years" or "the longest (best-case) survival" (Hagerty et al., 2004; Kiely et al., 2011).

	Stage IB	Stage IIB	Stage IIIA	Stage IIIB	Stage IVA1	Stage IVA2	Stage IVB
5 y OS, In General (%)	85.8	62.2	59.7	54.0	52.5	34.0	23.3
5 y OS, Best Case	88.8	67.9	67.6	63.4	61.0	46.3	39.7
5 y OS; Worst Case	82.1	56.0	50.7	43.3	43.2	22.1	10.0

Figure 1. Pooled 5-year OS in different stages of MF. The fraction of survivors was estimated from the pooled HRs for each stage. HR, hazard ratio; MF, mycosis fungoides; OS, overall survival.

PROGNOSTIC FACTORS IN SS: WORSE SURVIVAL

- **Advanced age** (Agar et al., 2010;Diamandidou et al., 1999; Foulcet al., 2003; Kim et al., 2003; Kubicaet al., 2012; Talpur et al., 2012)
- **Short duration of skin lesions before diagnosis of SS** (Foulc et al., 2003)
- **Previous history of mycosis fungoides** (Bernengo et al., 1998; Kubica et al., 2012)
- **Elevated serum lactate dehydrogenase levels** (Agar et al., 2010; Bernengo et al., 1998; Diamandidou et al.,1999; Foulc et al., 2003; Kubica et al.,2012; Talpur et al., 2012)
- **Degree of nodal involvement** (Diamandidou et al., 1999; Kim et al., 2003)
- **Factors reflecting blood tumor burden such as increased leukocyte counts** (Bernengo et al., 1998; Talpur et al.,2012; Vidulich et al., 2009) **or high Sézary cell counts** (Bernengo et al., 1998).

SUGGESTED TREATMENT REGIMENS[a,b]

SYSTEMIC THERAPIES		
	Preferred Regimens (alphabetical order)	**Other Recommended Regimens**
SYST-CAT A	• Brentuximab vedotin[i,j,k] • Bexarotene[h] • Extracorporeal photopheresis (ECP)[l] • Interferons (IFN-alfa-2b[m] or IFN-gamma 1b) • Methotrexate (≤50 mg q week) • Mogamulizumab[n] • Romidepsin[h] • Vorinostat[h]	• Acitretin[h] • All-trans retinoic acid[h] • Isotretinoin [13-cis-retinoic acid][h]
SYST-CAT B	• Brentuximab vedotin[i,j,k] • Gemcitabine • Liposomal doxorubicin • Pralatrexate (low-dose or standard dose)	

COMBINATION THERAPIES (alphabetical order)	
Skin-directed + systemic	• Phototherapy + ECP[l] • Phototherapy + Interferon (IFN-alfa-2b[m] or IFN-gamma 1b) • Phototherapy + retinoid • TSEBT + ECP[l]
Systemic + systemic	• ECP[l] + Interferon (IFN-alfa-2b[m] or IFN-gamma 1b) • ECP[l] + retinoid • ECP[l] + retinoid + Interferon (IFN-alfa-2b[m] or IFN-gamma 1b) • Retinoid + Interferon (IFN-alfa-2b[m] or IFN-gamma 1b)

ERYTHRODERMIC DISEASE/SÉZARY SYNDROME		
	Preferred Regimens	**Other Recommended Regimens**
Low-intermediate burden (eg, absolute Sézary cell [ASC] count <5 K/mm³)	• Combination therapies (see above) • SYST-CAT A ± skin-directed therapies (skin-generalized) (See MFSS-A 2 of 6)	• SYST-CAT B ± skin-directed therapies (skin-generalized) (See MFSS-A 2 of 6) • Alemtuzumab[k,p] • Pembrolizumab[q,r]
Higher burden (eg, ASC >5 K/mm³)	• Combination therapies (see above) • Mogamulizumab ± skin-directed therapies (skin-generalized)[h] • Romidepsin ± skin-directed therapies (skin-generalized)[h]	• SYST-CAT A (options not listed under preferred regimens) (See MFSS-A 2 of 6) • SYST-CAT B (See MFSS-A 2 of 6) • Alemtuzumab[k,p] • Pembrolizumab[q,r]

SEZARY SYNDROME
ITALIAN GROUP FOR CUTANEOUS LYMPHOMAS

Time Course, Clinical Pathways, and Long-Term Hazards Risk Trends of Disease Progression in Patients With Classic Mycosis Fungoides

A Multicenter, Retrospective Follow-Up Study From the Italian Group of Cutaneous Lymphomas

Pietro Quaglino, MD[1]; Nicola Pimpinelli, MD[2]; Emilio Berti, MD[3]; Piergiacomo Calzavara-Pinton, MD[4]; Giuseppe Alfonso Lombardo, MD[5]; Serena Rupoli, MD[6]; Mauro Alaibac, MD[7]; Ugo Bottoni, MD[8,9]; Angelo Carbone, MD[10]; Paolo Fava, MD[1]; Michele Fimiani, MD[11]; Angela Maria Mamusa, MD[12]; Stefano Titli, MD[1]; Pier Luigi Zinzani, MD[13]; Maria Grazia Bernengo, MD[1]; and On behalf of the Gruppo Italiano Linfomi Cutanei (GILC)

BACKGROUND: Mycosis fungoides (MF) is an indolent primary cutaneous T-cell lymphoma. To the authors' knowledge, no data currently are available regarding the evolution over time of the risk of developing specific pathways of disease progression. **METHODS:** This retrospective study analyzed 1422 patients with MF who were diagnosed and followed from 1975 through 2010 in 27 Italian Study Group for Cutaneous Lymphoma centers. The primary objectives were to ascertain the time course, pathways, and hazards risk trends of cutaneous/extracutaneous disease progression; to evaluate whether different tumor-lymph node-metastasis-blood (TNMB) stages have different pathways of disease progression; and to analyze differences between tumor-stage and erythrodermic MF with regard to clinical onset, disease evolution, and prognosis. The secondary objective was to provide a further validation for the revised International Society for Cutaneous Lymphomas and the Cutaneous Lymphoma Task Force of the European Organization of Research and Treatment of Cancer (ISCL/EORTC) classification. **RESULTS:** The median follow-up was 14.5 years; stage progression occurred in 29.7% of patients and blood involvement was the most frequent extracutaneous site of disease progression. Patients with stage IA to stage IB disease demonstrated a steady low annual incidence of disease progression to tumor-stage (1%-2%); patients with stage IIA disease had a higher risk within the first years (up to 9.4%). Erythroderma evolved with a significantly higher frequency from patches/plaques (13.9%-28.2%) than tumors ($P = .028$ and $P = .013$, respectively). Hazards rates of extracutaneous involvement were low (< 1%). T classification was found to be associated with extracutaneous involvement site, tumor-stage disease with lymph node/

AQ7

	Stage I	Stage II	Stage III	Stage IV
	13.8%	-	-	-
Topical steroids	16.7%	3.3%	9.3%	-
Phototherapy alone	43.2%	24.2%	9.2%	2.6%
Phototherapy + IFN	9.7%	3.3%	2.1%	-
Phototherapy + retinoids	0.9%	3.3%	2.8%	3.1%
Acitretin	2.5%	2.6%	-	-
Bexarotene	0.2%	4.4%	9.2%	4.2%
IFN	8.9%	12.1%	23.4%	10%
Local RT	2.3%	16.5%	2.1%	6.7%
TSET	0.1%	1.8%	-	3.3%
Monochemotherapy[a]	1.7%	15.7%	22%	30%
ECP	-	7.7%	13.3%	16.7%
Polichemotherapy[b]	-	5.1%	6.4%	23.3%

ECP: extracorporeal photochemotherapy; IFN: interferon; RT: radiotherapy; TSET: Total Skin Electron beam Therapy

[a]: includes methotrexate, fludarabine, gemcitabine, liposomal pegylated doxorubicin

[b] : CHOP or CHOP-like regimens were performed in the majority of patients

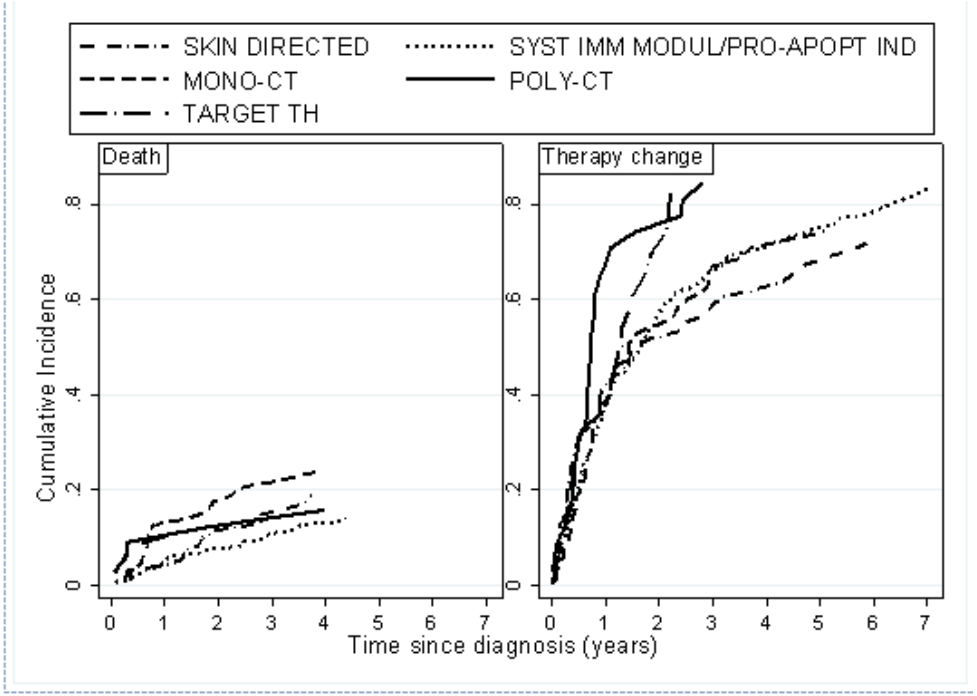
Cumulative incidence curves for death and change of therapy considered as competing risk events by first treatment line



Fine and Gray's test
p=0.1492

p=0.118

first-line treatment was selected as independent prognostic variable (p=0.008), both mono- and poly-chemotherapy being associated with higher mortality.

Table V. Principles of therapy for Sézary syndrome

- Use disease burden and rapidity of progression as determinants of approach to therapy
- Preserve immune response whenever possible
- Use immunomodulatory therapy before chemotherapy unless burden of disease or failure of prior such therapies warrants otherwise
- Always consider combination therapy, particularly systemic immunomodulatory plus skin-directed treatments, which in general has greater efficacy than monotherapy
- Consider potential *Staphylococcus* infection as cause of worsening disease and maintain low threshold for use of systemic antibiotics to prevent life-threatening sepsis
- Preserve quality of life by aggressive treatment of pruritus

Sézary syndrome: Immunopathogenesis, literature review of therapeutic options, and recommendations for therapy by the United States Cutaneous Lymphoma Consortium (USCLC)

Sézary syndrome (SS) has a poor prognosis and few guidelines for optimizing therapy. The US Cutaneous Lymphoma Consortium, to improve clinical care of patients with SS and encourage controlled clinical trials of promising treatments, undertook a review of the published literature on therapeutic options for SS. An overview of the immunopathogenesis and standardized review of potential current treatment options for SS including metabolism, mechanism of action, overall efficacy in mycosis fungoides and SS, and common or concerning adverse effects is first discussed. The specific efficacy of each treatment for SS, both as monotherapy and combination therapy, is then reported using standardized criteria for both SS and response to therapy with the type of study defined by a modification of the US Preventive Services guidelines for evidence-based medicine. Finally, guidelines for the treatment of SS and suggestions for adjuvant treatment are noted. (J Am Acad Dermatol 2011;64:352-404.)

Key word: Sézary syndrome.
